

## Node pool snapshot

- Let you take a configuration snapshot of your node pool and then build new node pools or new clusters based on that snapshot, for as long as that configuration and the Kubernetes version are supported
- The source node pool's configuration information, including the node image version, Kubernetes version, OS type, and OS SKU, will be contained in the snapshot, an Azure resource
- The following can be performed with the resulting snapshot:
  - create a new node pool or cluster based on it
  - upgrade the Kubernetes version and node image of that snapshot
- Limitations/considerations:
  - When you create a node pool or cluster from a snapshot, you need to use a VM from the same virtual machine family as the snapshot
  - The region where the source node pool is located must be used to create and use snapshots
