

Azure CNI network plugin

- Also known as advanced network plugin
- `--network-plugin azure`
- IP address assignment:
 - Nodes: from AKS subnet
 - Pods:
 - from AKS subnet (traditional)
 - IPs get preallocated based on each node based on `maxPods` parameter
 - 1 IP for the node + pod IPs (as per `maxPods` parameter)
 - from a separate pod dedicated subnet in AKS's VNET (dynamic allocation of IPs and enhanced subnet)
 - IPs are assigned from the pod dedicated subnet
- Pod-to-pod communication: direct, with no additional hop
- Pod to device inside the VNET: the device will see pod's IP as the source address
- Pod to device outside the VNET: the device will see node's IP as the source address, but that can be changed by modifying the masquerade rules

Azure CNI network plugin

10.224.0.0/12

AKS VNET

10.224.0.0/16

AKS Subnet

10.224.1.2

Another VNET
/ On prem

10.1.2.3

Node 0: 10.224.0.4

node

Pod A

pod

10.224.0.5

Pod B

pod

10.224.0.6

10.224.0.4 - 10.224.0.32

Node 1: 10.224.0.33

node

Pod C

pod

10.224.0.34

10.224.0.33 - 10.224.0.61

Azure CNI network plugin

- **Why would you choose Azure CNI?**
 - Pods receive IPs from the subnet -> Less hops -> Less latency
 - No need for managing UDRs
 - Communication happens mostly with devices outside of the cluster
 - Multiple clusters in the same subnet are allowed
 - You need features like Windows nodes, Azure Network Policy, Virtual Nodes
 - **What disadvantages apply to Azure CNI?**
 - Requires many IP addresses and IP address planning
 - Can lead to IP addresses exhaustion if the cluster grows
 - Upgrade or other operations require at least one buffer node that needs IPs so you will always need $\text{maxPods}+1$ IPs for this operations
- Mostly addressed by dynamic allocation of IPs and enhanced subnet which provides:
- Improved IP usage
 - Flexibility and scalability
 - High performance
 - Others
