

Exploring the AKS cluster – Kubernetes side

- **konnectivity-agent**

- Deployment running on worker nodes and communicates with konnectivity-server which is a container on the API server. Their goal is to create a tunnel of communication that allows the API server and kubelet to securely communicate via TLS encryption
- Together with other components, they form what was previously known as api-network-proxy
- Responsible for functionalities like: log retrieval (kubectl logs), connect or run commands inside a container (kubectl exec), port forwarding (kubectl port-forward), admission controller webhooks
- Needs port 10250 which is used by the kubelet for proper functionality inside the AKS cluster
