

Exploring the AKS cluster – Kubernetes side

- **kube-proxy**
 - Network proxy that runs on each node, so it is installed as a DaemonSet in AKS
 - Responsible for maintaining network rules on nodes and handling network traffic to and from pods
 - You may have one or more pods for your application, but that pod, or pods may be recreated. It is recommended to expose that pod or pods via a Kubernetes service, which will route the traffic to that pod or pods. But you may ask how that is achieved. Well, kube-proxy configures the iptables rules on each node to forward traffic to the pods exposed by that service. Kube-proxy obtains this information directly from the API server
