

Exploring the AKS cluster – Azure infrastructure side

- **Network Security Group (NSG)**

- Used to filter inbound and outbound network traffic for Azure resources by using security rules that allow or deny that traffic based on source, destination, port, and protocol
- It's not mandatory to use NSG in AKS, but for an AKS cluster created with default settings, an NSG with default rules will be assigned at the AKS Subnet level. These rules are automatically added to any NSG, whether it is for AKS or not, and they cannot be removed. The goal of these default rules is to allow essential traffic and block potential malicious traffic from the Internet
- Security rules can affect the traffic inside a subnet; thus, rules that may block AKS intra-subnet traffic should not be created
- It is important to know that AKS allows the customization of NSGs on custom subnets, which are subnets that were not created automatically by AKS
