

Exploring the AKS cluster – Azure infrastructure side

- **Route Table (RT)**

- Azure routes by default traffic flow across subnets, VNETs, on-premises networks, and the Internet, but a route table can be used to specify how packets should be routed
- A use case is that route tables can be associated at subnet the level and, each packet leaving a subnet is handled based on the associated route table, which contains routes that can send traffic to hops like “Virtual network gateway”, “Virtual Network”, “Virtual appliance”, “Internet” or “None” which is used to drop traffic
- Azure allows you to associate a route table with multiple subnets, but there are use cases when that is not recommended, for example in AKS when using the network plugin kubenet, which is the default one. In any case, a subnet cannot have more than a route table assigned
- In AKS, for kubenet, the default network plugin, the route table is used to distribute the traffic from the pods to the nodes. The routes are automatically managed by AKS as you add or remove nodes
- Another use case for AKS is to forward the traffic to a firewall
