

A deeper look into LoadBalancer Service in AKS

- Load Balancer service: Provides an externally IP address for accessing the service through a cloud provider load balancer that usually has a single, static IP address
- Azure automatically provisions and managed the associated Azure resources
- To perform changes at Load Balancer level, we need to modify the Kubernetes Load Balancer service, not the Azure resources
- These changes should be performed by adding or modifying fields or annotations
- Annotation: used to provide additional context and information
