

Connect to AKS nodes - run-command invoke

“az vmss run-command invoke”

- a convenient tool that helps you interact with VMSS instances by allowing you to run commands or scripts without the need to connect to the instances

Limitations/considerations:

- Only the latest 4,096 bytes are printed
- On Linux, scripts automatically execute as an elevated user
- One script could run at a time and a running script cannot be canceled
- Outbound connectivity from the VM is required to return the results of the script
- Others

Example:

```
az vmss run-command invoke -g <infra/MC-resource-group> -n <vmss-name> --instance-id <instance-id> --command-id RunShellScript --query 'value[0].message' -otsv --scripts "nc -vz microsoft.com 443"
```

- **-g, -n** and **--instance-id**: identifiers to specify for which instance we would like to run the command
- **--command-id RunShellScript**: This is the command to be executed on the virtual machine scale set, which in this case is a shell script
- **--query 'value[0].message'**: help you get specific output from a command that was run on a virtual machine scale set instance. In this example, it chooses the first object in the output array's "message" field
- **-otsv**: This specifies the output format of the command, which in this case is tab-separated values
- **--scripts "nc -vz microsoft.com 443"**: the command itself that is executed in this instance and determines whether microsoft.com can be reached on port 443
