

A summary about monolithic and microservices architectures

Monolithic architecture:

- all functionalities of the app exist in a single code base
- easier to deploy, but becomes too large, difficult to manage, and needs redeployment for every small change, leading to downtime

Microservices architecture:

- each service is a separate unit
- more complex but provides more flexibility, scalability and it's easier to maintain
- when some change is performed, you only touch one microservice
- good fit for containers
